Brachiopod origins

This document provides a detailed discussion of analyses of the morphological dataset constructed to accompany Sun *et al.* [2018], and their results.

We first discuss the results presented in the main paper, which employ the algorithm described by Brazeau, Guillerme and Smith [2017a] for correct handling of inapplicable data in a parsimony setting, and explore how each character is reconstructed on an optimal tree.

For completeness, we also document the results of standard Fitch parsimony analysis, and the results of Bayesian analysis, neither of which treat inapplicable data in a logically consistent fashion.

6 CONTENTS

Chapter 1

The dataset

Analysis was performed on a new matrix of 35 early brachiozoan taxa, including hyoliths, tommotiids and mickwitziids, which were coded for 95 morphological characters (42 neomorphic, 53 transformational).

The dataset can be viewed and downloaded at Morphobank (project 2800), where each character is defined and its coding for each taxon discussed.

Characters are coded following the recommendations of Brazeau, Guillerme and Smith [Brazeau et al., 2017a]. In brief, we have employed reductive coding, using a distinct state to mark character inapplicability. Character specifications follow the model of Sereno [2007].

We have distinguished between neomorphic and transformational characters [sensu Sereno, 2007] by reserving the token 0 to refer to the absence of a neomorphic character. The states of transformational characters are represented by the tokens 1, 2, 3, ...

Following the recommendations of Brazeau, Guillerme and Smith [Brazeau et al., 2017a, supplementary discussion], we code the absence of neomorphic ontologically dependent characters [sensu Vogt, 2017] as absence, rather than inapplicability.

Chapter 2

Parsimony analysis

The phylogenetic dataset contains a high proportion of inapplicable codings (404/3325 = 12% of tokens), which are known to introduce error and bias to phylogenetic reconstruction ([Maddison, 1993, Brazeau et al., 2017a]). As such, phylogenetic search employed a new algorithm that correctly handles inapplicable data [Brazeau et al., 2017a]. This algorithm is implemented in the MorphyLib C library [Brazeau et al., 2017b], and phylogenetic search was conducted using the R package TreeSearch vo.0.8 [Smith, 2018].

Namacalathus is included in the matrix but has been excluded from analysis due to its potentially long branch, which is likely to mislead analysis.

2.1 Search parameters

Heuristic searches were conducted using the parsimony ratchet [Nixon, 1999] under equal and implied weights [Goloboff, 1997] with a variety of concavity constants. The consensus tree presented in the main manuscript represents a strict consensus of all trees that are most parsimonious under one or more of the concavity constants (k) 2, 3, 4.5, 7, 10.5, 16 and 24, an approach that is known to produce higher accuracy than equal weights at any fixed level of precision [Smith, 2017].

2.2 Analysis

2.2.1 Load data

2.2.2 Generate starting tree

Dailyatia is used as an outgroup.

2.2.3 Implied weights analysis

```
for (k in kValues) {
  iw.tree <- IWRatchet(start.tree, iw_data, concavity=k,</pre>
                       ratchHits = 60, searchHits=55,
                       swappers=list(RootedTBRSwap, RootedSPRSwap, RootedNNISwap),
                        verbosity=0)
  score <- IWScore(iw.tree, iw_data, concavity=k)</pre>
  # Write single best tree
  write.nexus(iw.tree, file=paste0("TreeSearch/hy_iw_k", k, "_", signif(score, 5), ".nex", collapse='')
  suboptFraction = 0.02
  iw.consensus <- IWRatchetConsensus(iw.tree, iw_data, concavity=k,</pre>
                  swappers=list(RootedTBRSwap, RootedNNISwap),
                  searchHits=4,
                  suboptimal=score * suboptFraction,
                  nSearch=150, verbosity=0L)
  write.nexus(iw.consensus, file=paste0("TreeSearch/hy_iw_k", k, "_", signif(IWScore(iw.tree, iw_data,
}
```

Character 85 - 'Lophophore: tentacle rows per side: trocholophe stage'

1: Adbalial and ablabial row

?: Ambiguous

Character 86 - 'Lophophore: tentacle rows per side: post-trocholophe stage'

Character 86 - 'Lophophore: tentacle rows per side: post-trocholophe stage'

0: Absent1: Present

Character 87 - 'Lophophore: Median tentacle in early development'

Character 87 – 'Lophophore: Median tentacle in early development'

Character 88 - 'Lophophore: forms closed loop'

1: Diverging laterally

2: Closed loop

?: Ambiguous

Character 88 - 'Lophophore: forms closed loop'

Character 89 - 'Lophophore: coiling direction'

1: Anteriad2: Posteriad∴ ?: Ambiguous

Character 89 - 'Lophophore: coiling direction'

Character 90 - 'Lophophore: adjustor muscle'

0: Absent
1: Present

Character 90 - 'Lophophore: adjustor muscle'

Character 91 - 'Prominent pharynx'

0: Absent
1: Present

Character 91 - 'Prominent pharynx'

Character 92 - 'Anus'

1: Absent: digestive tract is blind sac

2: Present: through-gut

-- ?: Ambiguous

Character 92 - 'Anus'

0: Not migrated: straight gut with posterior anus

1: Migrated: anus has migrated posteriad to create U-shaped gut

?: Ambiguous

Character 93 - 'Anus: migration'

Character 94 - 'Anus: migration: within ring of tentacles'

Character 94 - 'Anus: migration: within ring of tentacles'

Character 95 - 'Anus: migration: position'

Character 95 - 'Anus: migration: position'

These reconstructions were created using the *Inapp R* package [Brazeau et al., 2017a].

Full character definitions can be found by browsing the morphological dataset on MorphoBank (project 2800).

Chapter 4

Fitch parsimony

Parsimony search was conducted in TNT v1.5 [Goloboff and Catalano, 2016] using sectorial and ratchet heuristics under equal and implied weights. We acknowledge the Willi Hennig Society for their sponsorship of the TNT software.

4.1 Implied weights

The consensus of all implied weights runs is not very well resolved:

4.1. IMPLIED WEIGHTS

This lack of resolution is largely a product of a few wildcard taxa, which obscure relationships that are nevertheless present in all most parsimonious trees:

4.1.1 Paterinids included

4.1.2 Paterinids excluded

4.2 Equal weights

Figure 4.1: TNT implied weights consensus

Figure 4.2: TNT implied weights consensus

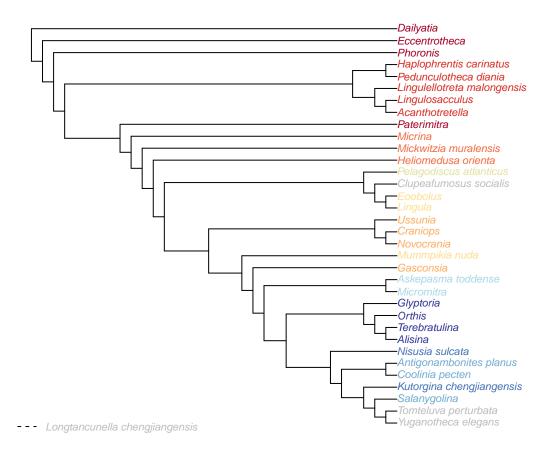

Figure 4.3: TNT Equal weights consensus

Chapter 5

Bayesian analysis

Bayesian search was conducted in MrBayes v3.2.6 [Ronquist et al., 2012] using the Mk model [Lewis, 2001] with a gamma parameter:

```
lset coding=variable rates=gamma;
```

Branch length was drawn from a dirichlet prior distribution, which is less informative than an exponential model [Rannala et al., 2012], but requires a prior mean tree length within about two orders of magnitude of the true value [Zhang et al., 2012]. To satisfy this latter criterion, we specified the prior mean tree length to be equal to the length of the most parsimonious tree under equal weights, using a Dirichlet prior with T=1, $T=1/(equal\ weights\ tree\ length\ /\ number\ of\ characters),\ =c=1$:

```
prset brlenspr = unconstrained: gammadir(1, 0.33, 1, 1);
```

Neomorphic and transformational characters [sensu Sereno, 2007] were allocated to two separate partitions whose proportion of invariant characters and gamma shape parameters were allowed to vary independently:

```
charset Neomorphic = 2\ 3\ 5\ 10\ 13\ 14\ 18\ 19\ 24\ 25\ 29\ 30\ 32\ 34\ 36\ 37\ 38\ 39\ 40\ 43\ 50\ 51\ 53\ 54\ 55\ 60\ 63\ 64\ 67\ 70\ 72\ 73\ 76\ 77\ 78\ 79\ 84\ 88\ 89\ 92\ 94\ 95;
```

charset Transformational $= 1\ 4\ 6\ 7\ 8\ 9\ 11\ 12\ 15\ 16\ 17\ 20\ 21\ 22\ 23\ 26\ 27\ 28\ 31\ 33\ 35\ 41\ 42\ 44\ 45\ 46\ 47\ 48\ 49\ 52\ 56\ 57\ 58\ 59\ 61\ 62\ 65\ 66\ 68\ 69\ 71\ 74\ 75\ 80\ 81\ 82\ 83\ 85\ 86\ 87\ 90\ 91\ 93;$

partition chartype = 2: Neomorphic, Transformational;

```
set partition = chartype;
```

```
unlink shape=(all) pinvar=(all);
```

Neomorphic characters were not assumed to have a symmetrical transition rate – that is, the probability of the absent \rightarrow present transition was allowed to differ from that of the present \rightarrow absent transition, being drawn from a uniform prior:

```
prset applyto=(1) symdirihyperpr=fixed(1.0);
```

Four MrBayes runs were executed, each sampling eight chains for 1 000 000 generations, with samples taken every 500 generations:

```
mcmcp ngen=1000000 samplefreq=500 nruns=2 nchains=8;
```

The first 10% of samples were discarded as burn-in (burninfrac=0.1), and a posterior tree topology was derived from the combined posterior sample of both runs.

Convergence was indicated by PSRF = 1.00 and an average estimated sample size of > 500 for each parameter:

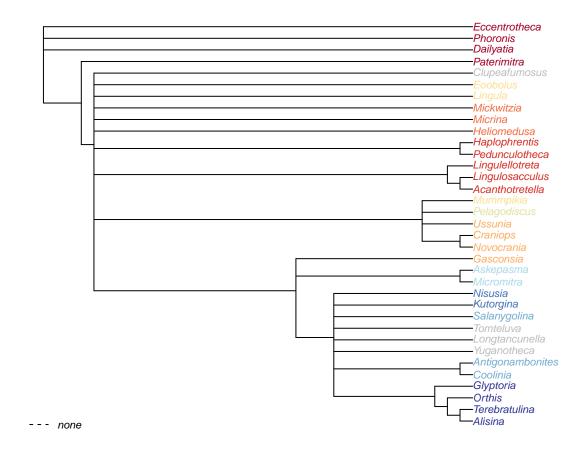

Figure 5.1: Bayesian analysis, posterior probability > 50%

Table 5.1: (#tab:MrBayes parameter summary)MrBayes parameter estimates (.pstat file)

Parameter	Mean	Variance	Lower	Upper	Median	minESS	avgESS	PSRF

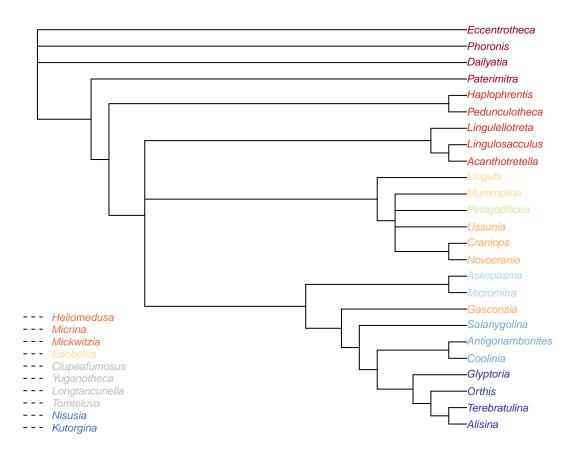

Figure 5.2: Bayesian analysis, posterior probability > 50%

It's interesting to note that the clade of hyoliths + lingulellotretids (+ relatives) is resolved as a grade under Bayesian analysis.

In parsimony analysis, these taxa are always resolved as a clade when inapplicable data is correctly handled; they instead resolve as a grade under certain conditions under the standard Fitch algorithm (which mishandles inapplicable data).

We suggest that the failure of Bayesian analysis to recover this group as a clade may reflect inappropriate handling of inapplicable data in MrBayes, though at present (and until the algorithms used in a likelihood context are improved) it is difficult to test this hypothesis.

The same goes for the position of *Gasconsia*, which is widely held to have an affinity with the craniid brachiopods, and is recovered in such a position using the inapplicable-safe parsimony algorithm (but not always when the standard Fitch parsimony algorithm is used).
